

# Covering spaces of an elliptic curve that ramify in precisely one point

Ane Anema

6 December 2012

# Outline

- 1 Topological perspective
- 2 Algebraic example
- 3 Family of branched covering spaces
- 4 Conclusions

Torus  $T$ 

$$\pi(T) \cong \mathbb{Z} \times \mathbb{Z}$$

Punctured torus  $S$ 

$$\pi(S) \cong \mathbb{Z} * \mathbb{Z}$$

- Let  $\tilde{S}$  and  $\tilde{T}$  be the universal covering spaces of  $S$  and  $T$ .

### Theorem

Let  $H \subset \pi(S)$  be a subgroup and  $Y \rightarrow T$  be the analytic continuation of  $\tilde{S}/H \rightarrow S$ . Then

$Y \rightarrow T$  unramified  $\iff H$  normal,  $\pi(S)/H$  abelian.

- A covering space of the torus is normal and its group of deck transformations is abelian.
- Consider

$$\begin{array}{ccccc}
 \tilde{S} & \longrightarrow & \tilde{S}/[\pi(S), \pi(S)] & \longrightarrow & S \\
 & & \downarrow & & \downarrow \\
 & & \tilde{T} & \longrightarrow & T
 \end{array}$$

- Let  $a, b$  be generators of  $\pi(S)$ .
- Define  $\phi : \langle a, b \rangle \rightarrow S_3$  as

$$a \mapsto (12) \quad \text{and} \quad b \mapsto (23).$$

- Consider  $X \rightarrow S$  corresponding to  $H = \ker \phi$ , which
  - has six sheets,
  - can be analytically continued to  $Y \rightarrow T$ , and
  - has  $\pi(S)/H \cong S_3$ .
- Let  $X' \rightarrow S$  correspond to  $H' = \phi^{-1}(\langle\langle(12)\rangle\rangle)$ , then
  - has three sheets,
  - can be analytically continued to  $Y' \rightarrow T$ , and
  - $H'$  is not normal.

- Let  $k$  be an algebraically closed field of char  $k \neq 2, 3$ .
- Consider the elliptic curve

$$E : y^2 = x^3 - 2ax^2 + (a^2 - 4b)x$$

over  $k$  with  $a, b \in k$  such that  $b \neq 0$  and  $a^2 \neq 4b$ .

- The idea is as follows

- Consider the elliptic curve over  $k$

$$E' : \eta^2 = \xi^3 + a\xi^2 + b\xi.$$

- Let  $\phi : E' \rightarrow E$  be an isogeny of degree two such that

$$\ker \phi = \{O', T'\},$$

where  $T' = (0, 0) \in E'$  is a point of order two.

- Write  $C$  for the curve that corresponds to the splitting field of

$$F = X^3 - \xi \in k(E')[X]$$

and  $\chi : C \rightarrow E'$  for the morphism induced by  $k(E') \subset k(C)$ .

## The algebraic analog

- Since the coordinate function  $\xi$  has

$$\operatorname{div} \xi = 2T' - 2O',$$

then  $\chi : C \rightarrow E'$  branches only above  $O'$  and  $T'$ , where it has ramification index three.

- Choose the isogeny  $\phi : E' \rightarrow E$  as

$$(\xi, \eta) \mapsto \left( \frac{\eta^2}{\xi^2}, \frac{\eta(b - \xi^2)}{\xi^2} \right).$$

- So  $k(E') = k(E)(\xi)$  and  $k(C) = k(E)(s)$ , where  $s^3 = \xi$ .
- Extension  $k(C)$  of  $k(E)$  is Galois with

$$\operatorname{Gal}(k(C)/k(E)) \cong S_3,$$

because  $s$  has minimum polynomial  $X^6 + (a - x)X^3 + b$

$$(X - s)(X - s^2)(X - s^3) \left( X - \frac{\sqrt[3]{b}}{s} \right) \left( X - \frac{\sqrt[3]{b}}{s^2} \right) \left( X - \frac{\sqrt[3]{b}}{s^3} \right)$$

- Let  $D$  be the curve with function field  $k(C)^{\{\text{id}, \tau\}}$ .

### Theorem

*The curve  $D$  is given by the equation*

$$\beta^2 = (\alpha^3 - 3c\alpha + a)(\alpha^2 - 4c)$$

*and has genus two.*

### Theorem

*The inclusion  $k(E) \rightarrow k(D)$  corresponds to a morphism  $\rho : D \rightarrow E$  given by*

$$(\alpha, \beta) \mapsto (\alpha^3 - 3c\alpha + a, -\beta(\alpha^2 - c))$$

*and ramifies only at infinity on  $D$ . At that point the ramification index is three.*

- Consider the following elliptic curve over  $\mathbb{C}$

$$B : 4a^3 + 27b^2 = 1$$

with unit element  $O$ .

- Also consider the elliptic curve over  $\mathbb{C}(B)$  defined by

$$E : y^2 = x^3 + ax + b.$$

- Let  $\ell$  be a prime number.
- Since  $\mathbb{C}(B)(E[\ell])$  is a finite extension of  $\mathbb{C}(B)$ , then it is a function field of a curve  $C_\ell$  over  $\mathbb{C}$ .
- The inclusion of function fields induces a morphism

$$\pi_\ell : C_\ell \rightarrow B.$$

### Theorem

*The morphism  $\pi_\ell : C_\ell \rightarrow B$  is Galois.*

### Theorem

*Let  $P \in C_\ell$ . If  $\pi_\ell(P) \neq O$ , then  $\pi_\ell$  is unramified at  $P$ .*

### Theorem

*Let  $P \in C_\ell$ . If  $\pi_\ell(P) = O$ , then*

- *$\pi_2$  is unramified at  $P$ ,*
- *$\pi_3$  is ramified at  $P$  with  $e_{\pi_3}(P) = 2$ ,*
- *$\pi_\ell$  is ramified at  $P$  for  $\ell > 3$  with  $e_{\pi_\ell}(P) = 2\ell$ .*

- Notice that  $G_\ell = \text{Gal}(\mathbb{C}(C_\ell)/\mathbb{C}(B))$  is a subgroup of  $\text{SL}_2(\mathbb{Z}/\ell\mathbb{Z})$ .

Case  $P \in C_\ell$  and  $\pi_\ell(P) = Q \neq O$ .

- Notice that  $E : y^2 = x^3 + ax + b$  over  $\mathbb{C}(C_\ell)$  is minimal at  $P$ .
- The extension  $\widehat{\mathbb{C}(C_\ell)}_P / \widehat{\mathbb{C}(B)}_Q$  is also Galois.
- The  $e_{\pi_\ell}(P)$  is equal to the degree of this extension.
- The reduction map restricts to an injective morphism

$$\psi : E \left( \widehat{\mathbb{C}(C_\ell)}_P \right) [\ell] \rightarrow \overline{E}_{\text{ns}}(\mathbb{C}),$$

which is Galois equivariant.

- If  $\tau \in \text{Gal} \left( \widehat{\mathbb{C}(C_\ell)}_P / \widehat{\mathbb{C}(B)}_Q \right)$ , then for all  $S \in E[\ell]$

$$\psi \circ \tau(S) = \tilde{\tau} \circ \psi(S) = \psi(S),$$

that is  $\tau(S) = S$ , hence  $\tau = \text{id}$ .

- Hence  $\pi_\ell$  is unramified at  $P$ .

Case  $P \in C_\ell$  and  $\pi_\ell(P) = O$  and  $\ell = 2$ .

- The polynomial  $x^3 + ax + b$  is irreducible over  $\mathbb{C}(B)$ .
  - Suppose reducible, then it has a zero in  $\mathbb{C}(B)$  with a pole of order one at  $O$  and regular elsewhere.
- The discriminant is a square, so the splitting field has degree at most three.
- Since the Galois group  $G_2 \cong \mathbb{Z}/3\mathbb{Z}$  is abelian, then

$$\pi_2 : C_\ell \rightarrow B$$

is unramified at  $P$ .

- The curve  $C_2$  again has genus one.

Case  $P \in C_\ell$  and  $\pi_\ell(P) = O$  and  $\ell \geq 3$ .

- Let  $\pi$  be a uniformizer at  $O$ , then  $E : y'^2 = x'^3 + \pi^4 ax' + \pi^6 b$  over  $\mathbb{C}(B)$  is minimal at  $O$ .
- Notice that  $E$  over  $\mathbb{C}(B)$  has additive reduction at  $O$ .
- Suppose that  $E$  over  $\mathbb{C}(C_\ell)$  also has additive reduction at  $P$ , then define  $K = \widehat{\mathbb{C}(C_\ell)}_P$  and consider

$$0 \rightarrow E_0(K) \rightarrow E(K) \rightarrow E(K)/E_0(K) \rightarrow 0$$

and the reduction map  $E_0(K) \rightarrow \overline{E}(\mathbb{C}) \cong (\mathbb{C}, +)$ , so that

$$\mathbb{Z}/\ell\mathbb{Z} \times \mathbb{Z}/\ell\mathbb{Z} \cong E[\ell] \hookrightarrow E(K)/E_0(K),$$

but this is impossible for  $l \geq 3$ . Therefore  $E$  over  $\mathbb{C}(C_\ell)$  has multiplicative reduction at  $P$ .

- Hence  $\pi_\ell$  is ramified at  $P$ .

Case  $P \in C_\ell$  and  $\pi_\ell(P) = O$  and  $\ell = 3$ .

- The 2-Sylow subgroup of  $SL_2(\mathbb{Z}/3\mathbb{Z})$  contains  $G_\ell$ , and is isomorphic to the quaternion group  $\{\pm 1, \pm i, \pm j, \pm k\}$ .
- Since  $\pi_3$  is ramified, then  $G_\ell$  is non-abelian, hence  $G_\ell$  is the 2-Sylow subgroup.
- Let  $H = \{\pm 1\}$  and consider

$$\mathbb{C}(B) \longrightarrow \mathbb{C}(C_\ell)^H \longrightarrow \mathbb{C}(C_\ell).$$

- The  $e_{\pi_3}(P) = 2$ , because  $G_\ell/H$  is abelian.
- Hence the genus of  $C_\ell$  is three.

Case  $P \in C_\ell$  and  $\pi_\ell(P) = O$  and  $\ell > 3$ .

- If  $E'$  is defined over  $\mathbb{C}(t)$  and  $j(E') = t$ , then

$$\text{Gal}(\mathbb{C}(t)(E'[\ell])/\mathbb{C}(t)) \cong \text{SL}_2(\mathbb{Z}/\ell\mathbb{Z}).$$

- Define

$$E' : y^2 = x^3 - \frac{27t}{t-1728}x - \frac{54t}{t-1728}$$

over  $\mathbb{C}(t)$ . It has  $j(E') = t$ .

- Let  $t = j(E) = 6912a^3$ , then

$$-\frac{27t}{t-1728} = \left(\frac{2a}{b}\right)^2 a \quad \text{and} \quad -\frac{54t}{t-1728} = \left(\frac{2a}{b}\right)^3 b.$$

- Thus  $E$  and  $E'$  are isomorphic over  $\mathbb{C}(a, b, c)$  for  $c^2 = \frac{2a}{b}$ .
- Hence  $\mathbb{C}(a, b, c, E[\ell]) = \mathbb{C}(a, b, c, E'[\ell])$ .

- Since  $SL_2(\mathbb{Z}/\ell\mathbb{Z})$  has no normal subgroups of index 2 and 3, then

$$G_\ell \cong SL_2(\mathbb{Z}/\ell\mathbb{Z}).$$

- Define an uniformizer  $\pi = \frac{2a}{b}$  at  $O$ .
- Consider  $E : y^2 = x^3 + ax + b$  over  $\mathbb{C}((\pi))$ .
- Compute

$$a = \pi^{-2}(-27 + b^{-2}) \quad \text{and} \quad b = \pi^{-3}(-54 + 2b^{-3})$$

- The curve  $E$  is equivalent to

$$E : y^2 = x^3 + (-27 + b^{-2})x + (-54 + 2b^{-3})$$

over  $\mathbb{C}((c))$  with  $c^2 = \frac{2a}{b}$ . Note that  $\Delta = c^{12}$ .

- Indeed  $E$  has multiplicative reduction modulo  $c$

$$\bar{E} : y^2 = x^3 - 27x - 54 = (x + 3)^2(x - 6).$$

- Use the theory of the Tate curve.
- There is a  $q \in \mathbb{C}((c))$  such that for every finite  $L/\mathbb{C}((c))$  there exists a Galois equivariant isomorphism

$$L^*/q^{\mathbb{Z}} \rightarrow E(L).$$

Moreover  $v(q) = v(\Delta) = 12$ .

- Hence  $\mathbb{C}((c))(E[\ell]) = \mathbb{C}((c))(\sqrt[\ell]{q})$ .
- Consider

$$\begin{array}{ccc}
 & \mathbb{C}((c))(E[\ell]) & \\
 & \nearrow & \nwarrow \\
 \mathbb{C}((\pi))(E[\ell]) & & \mathbb{C}((c)) \\
 & \nwarrow & \nearrow \\
 & \mathbb{C}((\pi)) & 
 \end{array}$$

- In fact  $\mathbb{C}((\pi))(E[\ell]) = \mathbb{C}((c))(E[\ell])$ , because
  - Recall  $E$  has multiplicative reduction over  $\mathbb{C}((\pi))(E[\ell])$ .
  - The coefficient  $a$  transforms as  $au^4$  for some  $u$ .
  - Multiplicative reduction requires

$$0 = v(u^4 a) = 4v(u) - v(a) = 4v(u) - 2e$$

with  $e$  the ramification index. Therefore  $e$  is even.

- Hence  $c \in \mathbb{C}((\pi))(E[\ell])$ .
- The ramification index of  $\pi_\ell$  at  $P$  is  $2\ell$ .
- Compute the genus

$$g(C_\ell) = 1 + \frac{(\ell^2 - 1)(2\ell - 1)}{4}.$$

Let  $\ell > 3$ . Adjoin all  $x$ -coordinates of points of order  $\ell$  to  $\mathbb{C}(B)$ .

- Denote this curve by  $D_\ell$ , then

$$C_\ell \longrightarrow D_\ell \longrightarrow B.$$

- Notice that  $\mathbb{C}(D_\ell) = \mathbb{C}(C_\ell)^H$  for  $H = \{\pm 1\}$ .
- Let  $Q \in D_\ell$  be a point above  $O$ .
- The ramification index of  $D_\ell \rightarrow B$  at  $Q$  is  $\ell$ , because
  - it is either  $\ell$  or  $2\ell$ , and
  - there is no cyclic subgroup of order  $2\ell$  in  $\mathrm{PSL}_2(\mathbb{Z}/\ell\mathbb{Z})$ .
- So the genus of  $D_\ell$  is

$$g(D_\ell) = 1 + \frac{(\ell^2 - 1)(\ell - 1)}{4}.$$

Let  $\ell > 3$ . Adjoin the  $x, y$ -coordinates of one point of order  $\ell$ .

- In this case the curve has
  - $\frac{\ell-1}{2}$  points above  $O$  with ramification index 2, and
  - $\frac{\ell-1}{2}$  points above  $O$  with ramification index  $2\ell$ .
- The curve has genus

$$1 + \frac{\ell(\ell-1)}{2}.$$

Let  $\ell > 3$ . Adjoin the  $x$ -coordinate of one point of order  $\ell$ .

- This curve has
  - $\frac{\ell-1}{2}$  unramified points above  $O$ , and
  - $\frac{\ell-1}{2}$  points above  $O$  with ramification index  $\ell$ .
- So the genus is

$$1 + \frac{(\ell-1)^2}{4}.$$

- Using algebraic topology determined a condition on when a branched covering space of the torus is ramified or not.
- Given examples of ramified branched covering spaces of the torus via topology, and their algebraic analogues.
- Constructed a family of branched covering spaces of  $4a^3 + 27b^2 = 1$  and computed the Galois group, the ramification indices and the genus.
